1. From physics to... Physics

Modern high energy physics (HEP) requires analysis. To make it possible several large scale objects are needed: from accelerators, detectors, data centers to the thousands of people involved to design and run the infrastructure. Here at CERN everything starts with physics by colliding particles and everything ends with the physics performed by analyzing the data acquired. But, to produce the necessary data, in the right amount, a long and complicated process, showed in figure 1.1, is involved. It is worth to briefly describe it to understand the reason of our work and where is it place inside it.

Data generation The process starts with **particle collisions** this lead to particle interactions that create some **intermediate product**. This intermediate product can not be directly observed, bit it decays in **particles** that go through the detectors. The intermediate product is divided in **X** and **Y**, X is what physicists are trying to study while Y is something that produces similar particles as Y but is not what they are looking for.

Data aquisition Detectors are split in two levels: **physics detector level** and **electronics level**. The physics level takes in input sensor readouts and produces an analog signal. This analog signal is the digitalized by the electronics level. This level also decides if the event is interesting or not, based on this the event is discarded or recorded. The event that survive this ends up dumped into **disks** and send to the **High level trigger**.

It is important to notice that these decision are taken in real time, to meet the throughput and timing requirements everything is built with **asics** and **fpgas** boards.

Data processing Data processing is performed both online and offline. The first step, called **local reconstruction**, in the offline data processing is to transform charges in physical quantities such as **energy**, **time**, and **position**. This operation is done channel by channel independently form each other. Then, information coming from different channel of the same detector are combined by the **cross channel clustering** into **local detector clusters**. The final step needed to obtain **particle objects** is the **cross detector clustering** in which data coming from different detector is combined. The particle object forms the dataset used by theoretical physicists to do physics.

High level trigger (HLT) The **HLT** belongs both to data acquisition and data processing, since it would not be correct to include it in one of this categories, it deserves a separate discussion. The HLT main purpose is to select interesting events before writing them to disk. In order to accomplish this, it runs the same code used for the offline processing, but **online** and with less features because of strict time constraints.

The main difference between **L1** and HLT is that L1 is implemented in hardware with no host while HLT is software based, it runs on hosts with accelerators used to speed-up the processing.

2. Local energy reconstruction

The HLT shares the same code used for offline data processing, thus the processing pipeline is more or less the same. The fundamental difference is that the output is used to perform event classification instead of data analysis. The table 2.1 shows how much time is spent in every

Figure 2.1: HLT processing pipeline

single step of the reconstruction process. Most of it is spent into tracking but after it, the second more time consuming step is HCAL+ECAL local reconstruction that takes $113ms$ corresponding to 24% of the total time. Given the time needed to perform this reconstruction even achieving a speedup of two would reduce the total processing time of more than 10%. This is my focus in this project try to reduce it as much as possible.

Figure 2.2: Data processing time share

Table 2.1: Time spent into the various HLT reconstruction steps

Step	Real-Time	Percentage
ECAL local reconstruction	38.9 ms	8.25%
HCAL local reconstruction	73.9 ms	15.67%
Jets/MET	14 ms	2.97%
E/Gamma	20.4 ms	4.33%
Muons	34.2 ms	7.25%
Pixel tracking	65.7 ms	13.93%
Full tracking	114.2 ms	24.22%
Vertex reconstruction	2.3 ms	0.49%
Particle Flow and Taus	36.8 ms	7.8%
HLT	14.7 ms	3.12%
Overhead	56.4 ms	11.96%
Total	471.5 ms	100%

2.1 Problem statement

As the name says the goal of this step is:

Claim: For each channel {given n charge readouts \rightarrow reconstruct the energy}.

Where in this case n is fixed to 10.

Translated into mathematical terms this means:

$$\begin{aligned} & \min(\|Px - b\|) \\ \text{where:} \\ & x = \text{energy vector} \\ & P : CHARGE \rightarrow ENERGY = \text{feature matrix} \\ & b = \text{charge vector} \end{aligned} \tag{2.1}$$

As shown in [1] the statement above is incomplete. A perfect mapping from charges to energy does not exist because signal from the shower does not dissipate within one time slice ($25ns$).

3. Conclusions

Write your conclusions here.

A. My First Appendix

In this file (appendices/main.tex) you can add appendix chapters, just as you did in the thesis.tex file for the 'normal' chapters. You can also choose to include everything in this single file, whatever you prefer.
